# **Dynamic Optimization**

Jesús Bueren

EUI

# Dynamic Optimization

- In this chapter we are going to characterize solutions to dynamic optimization problems
- In order to solve them, we are going to introduce discrete dynamic programming.
- Along our way, we are going to revise some mathematical concepts covered by Villanacci.
- References: The PhD Macro Book (Ch 4), Acemoglu (Ch 6), and SLP (Ch 4).

# Motivating the Recursive Formulation

#### A Cake Eating Problem

- We will go over a very simple dynamic optimization problem.
- Suppose that you are presented with a cake of size  $W_1$ .
- At each point in time  $t=1,2,\ldots,T$ , you can eat some of the cake but must save the rest.
- Let  $c_t$  be your consumption at time t and  $u(c_t)$  represent the flow of utility.
- u twice differentiable, strictly increasing, strictly concave,  $\lim_{c\to 0} u'(c) = \infty$ .
- Discount factor:  $0 < \beta < 1$

# The Sequential Formulation

#### A Cake Eating Problem

• The agent is solving:

$$\max_{\{c_{t}, W_{t+1}\}_{t=0}^{T}} \sum_{t=0}^{I} \beta^{t} u(c_{t})$$
s.t.  $c_{t} + W_{t+1} = W_{t} \ \forall t$ 
 $W_{T+1} \geq 0$ 

The Lagrangian associated to this problem is given by:

$$\mathcal{L} = \sum_{t=0}^{T} \beta^{t} u(c_{t}) + \sum_{t=0}^{T} \lambda_{t} (W_{t} - c_{t} - W_{t+1}) + \phi W_{T+1}$$

# The Sequential Formulation

#### A Cake Eating Problem

FOCs:

$$\beta^{t} u_{c}(c_{t}) = \lambda_{t}$$

$$\lambda_{t} = \lambda_{t+1}$$

$$\lambda_{T} = \phi$$

$$\phi \geq 0 \text{ with } \phi W_{T+1} = 0 \Rightarrow \beta^{T} u_{c}(c_{t}) W_{T+1} = 0$$

$$u'(c_{t}) = \beta u'(c_{t+1}) \ \forall t \in [0, T-1]$$

$$W_{T+1} = 0$$

• With the set of T intertemporal equations (euler equations), an initial condition and a terminal condition

#### A Cake Eating Problem

- In order to solve finite-horizon dynamic programming problems, we are going to proceed by backwards induction.
- For t = T, given the properties of u and the constraint, the optimal solution is given by:

$$c_T = W_T$$
$$u(c_T) = u(W_T)$$

#### A Cake Eating Problem

We define the value function at time T for the problem at time T as:

$$V_T(W_T) = \max_{c_T} u(c_T)$$
$$c_T + W_{T+1} = W_T$$

The optimal cake-saving decision is thus:

$$g_T(W_T)=0$$

and the value function is given by:

$$V_T(W_T) = u(W_T)$$

#### A Cake Eating Problem

• Now let's go to t = T - 1 given that we have solved the problem for t = T and define  $V_{T-1}$ .

$$V_{T-1}(W_{T-1}) = \max_{c_{T-1}, c_T, W_T, W_{T+1}} u(c_{T-1}) + \beta u(c_T)$$
s.t.  $c_{T-1} + W_T = W_{T-1}$ 

$$c_T + W_{T+1} = W_T$$

• Given that we already we know what is optimal to do in the next period, we can simplify the problem at T-1 as:

$$V_{T-1}(W_{T-1}) = \max_{c_{T-1}, W_T} u(c_{T-1}) + \beta V_T(W_T)$$
  
s.t.  $c_{T-1} + W_T = W_{T-1}$ 

#### A Cake Eating Problem

• Le's write the optimality conditions as:

$$u'(c_{T-1}) = \beta V'_T(W_T)$$
  
$$u'(c_{T-1}) = \beta u'_T(W_T)$$

- The solution coincides with the sequential formulation in the last period.
- We are in good track but what about previous periods?

#### A Cake Eating Problem

• Since it's going to be useful let's first derive the value of  $V'_{T-1}(W_{T-1})$  given the optimal cake saving decision  $g_{T-1}(W_{T-1})$  obtained from the previous FOC.

$$\begin{split} V_{T-1}(W_{T-1}) &= u(W_{T-1} - g_{T-1}(W_{T-1})) + \beta V_T(g_{T-1}(W_{T-1})) \\ \frac{\partial V_{T-1}(W_{T-1})}{\partial W_{T-1}} &= u_c(c_{T-1}) - u_c(c_{T-1}) \frac{\partial g_{T-1}(W_{T-1})}{\partial W_{T-1}} + \\ & \beta \frac{\partial g_{T-1}(W_{T-1})}{\partial W_{T-1}} \frac{V_T(W_T)}{\partial W_T} \\ \frac{\partial V_{T-1}(W_{T-1})}{\partial W_{T-1}} &= u_c(c_{T-1}) + \frac{\partial g_{T-1}(W_{T-1})}{\partial W_{T-1}} \Big(\beta \frac{V_T(W_T)}{\partial W_T} - u_c(c_{T-1})\Big) \\ \frac{\partial V_{T-1}(W_{T-1})}{\partial W_{T-1}} &= u_c(c_{T-1}) \end{split}$$

#### A Cake Eating Problem

• At T-2 the problem can be written as:

$$V_{T-2}(W_{T-2}) = \max_{c_{T-2}, W_{T-1}} u(c_{T-2}) + \beta V_{T-1}(W_{T-1})$$
  
s.t.  $c_{T-2} + W_{T-1} = W_{T-2}$ 

With FOCs:

$$u_c(c_{T-2}) = \beta \frac{\partial V_{T-1}(W_{T-1})}{\partial W_{T-1}} = \beta u_c(c_{T-1})$$

# Practical Dynamic Programming

#### Finite Horizon

- Define a discretized grid of cake:  $W \in \{W^1, \dots, W^{nkk}\}$ .
- Define  $V_T(W_T)$  for each  $W_T^i$  in the cake grid:  $V_T(W_T^i) = u(W_T^i)$  and  $g_T(W_T^i) = 0 \ \forall \ i \in \{1, \dots, nkk\}$
- Go to the previous period. We want to find  $g_{T-1}(W_{T-1})$
- Grid search: For each  $W_{T-1}^i$ ,  $i \in \{1, ..., nkk\}$ , the agent has i possible cake saving decisions  $W_T^j$  where  $j \in \{1, ..., i\}$ .
- Compute the value for each j:

$$V_{T-1}(W_{T-1}^i, W_{T-1}^j) = u(W_{T-1}^i - W_T^j) + \beta V(W_j)$$

and select the  $W_{T-1}^j$  which achieves the highest utility:  $j^*$ , set  $g_{T-1}(W_{T-1}^i) = W_T^{j^*}$  and  $V_{T-1}(W_{T-1}^i) = V_{T-1}(W_{T-1}^i, W_{T-1}^{j^*})$ 

• Move to period T-2

#### A Cake Eating Problem

- Suppose for the cake-eating problem, we allow the horizon to go to infinity.
- The main advantage of an infinite horizon is that the agent problem becomes stationary: the maximization problem at date t is exactly the same as in period t+1
- Unlike in finite horizon case, we don't have a terminal condition in the cake eating problem we will thus need to impose a transversality condition:

$$\lim_{t\to\infty}\beta^t u_c(c_t)W_{t+1}=0$$

if discounted marginal utility is positive, the amount of cake needs to go to zero to rule out over-accumulation

#### A Cake Eating Problem

One can consider solving the infinite horizon sequence given by:

$$\max_{\{c_{t}, W_{t+1}\}_{t=0}^{\infty}} \sum_{t=0}^{\infty} \beta^{t} u(c_{t})$$
s.t.  $c_{t} + W_{t+1} = W_{t} + y \ \forall \ t$ 

$$\lim_{t \to \infty} \beta^{t} u_{c}(c_{t}) W_{t+1} = 0$$

Written in recursive form:

$$V(W_t) = \max_{\{c_t, W_{t+1}\}} u(c_t) + \beta V(W_{t+1})$$
s.t.  $c_t + W_{t+1} = W_t + y$ 

$$\lim_{t \to \infty} \beta^t V(W_t) = 0$$
(2)

The transversality condition (2) is frequently avoided because assuming V being bounded, its is satisfied for  $\beta < 1$ .

#### A Cake Eating Problem

- Equation (1) is referred as the Bellman equation.
- It is a functional equation: the unknown represents as function.
- By FOCs:

$$u_c(c_t) = \beta \frac{\partial V(W_{t+1})}{\partial W_{t+1}}$$
(3)

• Let's define g(W) the optimal savings function associated with equation (1):

$$g(W_t) = \arg \max_{W_{t+1}} u(W_t + y - W_{t+1}) + \beta V(W_{t+1})$$

$$V(W_t) = u(W_t + y - g(W_t)) + \beta V(g(W_t))$$

#### A Cake Eating Problem

Provided that g is differentiable we can now compute:

$$\frac{\partial V(W_t)}{\partial W_t} = u_c(c_t) + \frac{\partial g(W_t)}{\partial W_t} \left( \beta \frac{\partial V(W_{t+1})}{\partial W_{t+1}} - u_c(c_t) \right)$$
$$\frac{\partial V(W_t)}{\partial W_t} = u_c(c_t) \Rightarrow \frac{\partial V(W_{t+1})}{\partial W_{t+1}} = u_c(c_{t+1})$$

Then we can write equation (3) as:

$$u_c(c_t) = \beta u_c(c_{t+1})$$

#### A Cake Eating Problem

- Under what conditions V exists? Is it unique?
- How to find V in the infinite horizon case?
- Is g a function or a correspondence? Is it differentiable?

# The Dynamic Programming Approach

- Buiding on the intuition gained from the cake eating problem, we now consider a more formal treatment of the dynamic programming approach to answer the previous questions.
- We begin with the nonstochastic case and then add uncertainty to the formulation.

# The Dynamic Programming Approach

- Consider the infinite horizon optimization problem of an agent with payoff function  $\tilde{\sigma}(s_t, c_t)$ .
- state vector:  $s_t$ ; control vector:  $c_t$ .
- Transition equation:  $s_{t+1} = \tilde{\tau}(s_t, c_t)$ .
- The state summarizes all the information from the past that is needed to make a forward-looking decision.
- $s \in \mathcal{S}$  and  $c \in \mathcal{C}(s)$ .
- Let  $\beta$  be the discount factor and assume  $0 < \beta < 1$ .

# The Dynamic Programming Approach

The sequential problem can be written as:

$$\max_{\{c_t\}_{t=0}^{\infty}} \sum_{t=0}^{\infty} \beta^t \tilde{\sigma}(s_t, c_t)$$
 $s.t. \ s_{t+1} = \tilde{\tau}(s_t, c_t)$ 
 $c_t \in \tilde{\mathcal{C}}(s_t)$ 

 We can rewrite the problem by imposing the law of motion of the state:

$$V^*(s_0) = \max_{\{s_{t+1}\}_{t=0}^{\infty}} \sum_{t=0}^{\infty} \beta^t \sigma(s_t, s_{t+1})$$
 s.t.  $s_{t+1} \in \mathcal{C}(s_t)$ ,

Where  $V^*$  denotes the highest possible value the the objective function can reach

• The basic idea of dynamic programming is to turn the sequential problem into a functional equation:

$$V(s) = \max_{s' \in \mathcal{C}(s)} \sigma(s, s') + \beta V(s)$$
 (4)

- Instead of choosing a sequence  $\{s_t\}_{t=0}^{\infty}$ , we choose a policy, which determines the control s' as a function of the state s.
- Given that V appears both in both sides of the equation 4 and thus it is defined recursively.
- Equation 4 is also referred as the Bellman equation after Richard Bellman, who was the first to introduce the dynamic programming formulation.
- A solution to the functional equation is thus a fixed point.

## Math Review

#### Brouwer's Fixed Point Theorem

- Let  $\mathcal{F}$  be a nonempty compact (closed and bounded) convex set.
- Let T be a continuous function that maps each point  $x \in \mathcal{F}$  to itself.
- Then T has a fixed point  $x^* \in \mathcal{F}$  such that  $T(x^*) = x^*$
- More questions:
  - To which set does V belong to?
  - Does the operator defined in the functional equation map each element of that set to itself?
  - Is the fixed point unique?

# Math Review

#### What is a Contraction Mapping?

• Let  $(\mathcal{M}, d)$  be a metric space where  $\mathcal{M}$  is a set and d is a metric.

A metric space is a set and a function such that for all  $x, y, z \in S$ :

- 1.  $d(x, y) \ge 0$ , with equality iff x = y
- 2. d(x, y) = d(y, x)
- $3. d(x,y) \leq d(x,z) + d(z,y)$
- Let  $T: \mathcal{M} \to \mathcal{M}$  be an function mapping  $\mathcal{M}$  into itself.
- If there exists a  $\beta \in (0,1)$  such that,

$$d(\mathit{Tz}_1, \mathit{Tz}_2) \leq \beta d(z_1, z_2) \ \forall \ z_1, z_2 \in S$$

then T is a **contraction mapping** with modulus  $\beta$ .

• In other words, a contraction mapping brings elements of the space  ${\cal M}$  uniformly closer to one another.

## Math Review

#### Contraction Mapping Theorem

Let  $(\mathcal{M},d)$  be a complete metric space and suppose  $T:\mathcal{M}\to\mathcal{M}$  is a contraction mapping.

A metric space is complete if every Cauchy sequence is a convergent sequence.

- A sequence  $\{x_n\}_{n=0}^{\infty}$  is a Cauchy sequence if for all  $\epsilon > 0$  there exists an  $N \in \mathbb{N}$  such that for all I, n > N,  $d(x_I, x_n) < \epsilon$
- A sequence  $\{x_n\}_{n=0}^{\infty}$  is a convergent sequence to  $\underline{x_0 \in \mathcal{M}}$  if for all  $\epsilon > 0$ , there exist here exists an  $N \in \mathbb{N}$  such that for any n > N,  $d(x_n, x_0) < \epsilon$
- Then, T has a **unique** fixed point  $\hat{z}$  and for any  $z_0 \in \mathcal{M}$ , and any  $n \in \mathbb{N}$  we have  $d(T^n z_0, \hat{z}) \leq \beta^n d(z_0, \hat{z})$ .
- That is there exists a unique  $\hat{z} \in \mathcal{M}$  such that

$$T\hat{z} = \hat{z}$$

and regardless of the starting guess  $z_0$ , the sequence  $\{T^n z_0\}_{n=0}^{\infty}$  converges to  $\hat{z}$ .

## Match Review

#### Blackwell's Sufficient Conditions for a Contraction

- Let  $s \in \mathcal{S}$  and  $(\mathcal{M}, d)$  be the metric space where  $\mathcal{M}$  is the set of bounded function equipped with the sup norm.
- Let  $T: \mathcal{M}(s) \to \mathcal{M}(s)$  satisfying:
  - 1. Monotonicity: If  $W(s) \ge Q(s)$ , for all  $s \in S$ , then  $TW(s) \ge TQ(s)$ .
  - 2. Discounting: for any constant k there exists  $\tilde{\beta} \in [0,1)$  such that  $T(W+k)(s) \leq T(W)(s) + \beta k$ .
- Then T is a contraction.

- In order to apply the Blackwell sufficient conditions, we need V to belong to the set of bounded functions.
- For this to be true, we need some assumption on the primitive objects.

- $\sigma(s_t, s_{t+1})$  needs to be bounded so that it does not yield infinite returns: we cannot compare two choices of  $s_{t+1}$  that deliver infinite value.
- With  $\beta \in (0,1)$  and bounded  $\sigma$ , the V will be bounded for the problems that we will see in this course.
- Problems might arise in models of growth: you would need growth in the return function to be "smaller" than the rate of discounting such that discounted returns are bounded.
- This assumption will allow us to define the set of V: the set of continuous bounded functions.
- Equipped with the supremum norm forms a complete metric space.

- If  $\sigma$  is continuous and  $\mathcal C$  is nonempty and compact (closed and bounded).
  - $\Rightarrow$  Unique value function satisfying the functional equation and therefore it is possible to find V(x) by an iterative process
    - 1. Select any initial value  $V_0(s) \ \forall s \in \mathcal{S}$ .
    - 2. Define a sequence of functions:

$$V_n(x) = \max_{s' \in \mathcal{C}(s)} \sigma(s, s') + \beta V_{n-1}(s)$$

3. The sequence  $\{V_0, V_1, \dots, V_n\}_{n=0}^{\infty}$  converges to V

- Even if V is unique it could be that the policy associated could be a correspondence unless we put further restrictions of  $\sigma$  and C:
  - 1.  $\sigma(s, s')$ : strictly concave, continuous, and differentiable.
  - 2. C(s): convex
  - $\Rightarrow$  We have a continuous and differentiable policy function
- The Enveloppe theorem holds:

$$\frac{\partial v(s)}{\partial s} = \frac{\partial \sigma(s, s')}{\partial s}$$

# Is T a Contraction?

Blackwell's Sufficient Conditions: Monotonicity

- Let  $Q(s) \leq W(s) \ \forall s \in \mathcal{S}$ .
- Let  $\phi_Q(s)$  be the policy function obtained from:

$$\phi_Q(s) = arg \max_{s' \in \mathcal{C}(s)} \sigma(s, s') + \beta Q(s')$$

Then,

$$TQ(s) = \sigma(s, \phi_Q(s)) + \beta Q(\phi_Q(s)) \le \sigma(s, \phi_Q(s)) + \beta W(\phi_Q(s))$$

$$= \max_{s' \in \mathcal{C}(s)} \sigma(s, s') + \beta W(s') = TW(s)$$

# Is T a Contraction?

Blackwell's Sufficient Conditions: Discounting

This property is easy to verify in the dynamic programming problem:

$$T(W+k)(s) = \max_{s' \in \mathcal{C}(s)} \sigma(s,s') + \beta(W(s')+k)$$
$$= TW(s) + \beta k$$

- In 1928 Frank Ramsey, a young mathematician, posed the problem: "How much of its income should a nation save?"
  and developed a dynamic model to answer this question.
- Economic agent (a social planner) producing output from labor and capital who must decide how to split production between consumption and capital accumulation.

#### The Planner's Problem

- Time is discrete.
- Production is given by  $y_t = f(k_t)$  where  $k_t$  is capital. f satisfies inada conditions.
- The planner's problem is given by:

$$\max_{\substack{\{c_t\}_{t=0}^{\infty}\{k_{t+1}\}_{t=0}^{\infty}}} \sum_{t=0}^{\infty} \beta^t u(c_t)$$
s.t.  $c_t + k_{t+1} \le f(k_t) + (1 - \delta)k_t \ \forall t$ 

#### The Planner's Problem

• Now let's write the planner's problem in recursive form:

$$V(k) = \max_{k' \in [0, f(k) + (1 - \delta)k]} u(f(k) + (1 - \delta)k - k') + \beta V(k')$$

• The solution is characterized by:

$$u_c(c) = \beta \frac{\partial V(k')}{\partial k'} = \beta \left( \frac{\partial f(k')}{\partial k'} + 1 - \delta \right) u_c(c')$$

#### The Planner's Problem

• In the one sector growth model we define the operator T to be:

$$TV(k) = \max_{k' \in [0, f(k) + (1 - \delta)k]} \{ u(f(k) + (1 - \delta)k - k') + \beta V(k') \}$$

- We want to argue that this operator has as unique fixed point using the contraction mapping theorem.
- Thus we are going to do it using Blackwell's sufficient conditions.

#### The Planner's Problem

· Monotonicity:

Let 
$$\phi_Q(k) = \arg\max_{k' \in \Gamma(k)} u(f(k) + (1-\delta)k - k' + \beta Q(k'))$$
 if  $Q(k) \leq W(k)$ , for all  $k$  then  $TQ(k) = u(f(k) + (1-\delta)k - \phi_Q(k)) + \beta V(\phi_Q(k))$   $\leq u(f(k) + (1-\delta)k - \phi_Q(k)) + \beta W(\phi_Q(k))$   $\leq TW(k)$ 

Discounting:

$$T(V+a)(k) = \max_{k' \in \Gamma(k)} \{ u(f(k) + (1-\delta)k - k') + \beta(V(k') + a) \}$$
$$= TV(k) + \beta a$$

#### Discrete State Methods

- There exists a variety of numerical methods to solve dynamic programming problems like the Ramsey problem (projection, perturbation, parameterized expectation).
- The need of numerical methods arises from the fact that dynamic programming problems generally do not have tractable closed form solutions.
- Because of their simplicity, we are going to focus on discrete-state space methods.

#### Discrete State Methods

- In this case, the value function is a finite dimensional object.
- For instance, if the state space is one dimensional and has elements  $S = s_1, s_1, \ldots, s_n$ , the value function is just a vector of n elements where each element gives the value attained by the optimal policy if the initial state of the system is  $s_n \in S$ .
- Drawback: curse of dimensionality.
  - If the the value function of an m-dimensional problem with n different points in each dimension is an array of  $n^m$  different elements and the computation time needed to search this array may be prohibitively high.

#### Value Function Iteration

- Given that Blackwell sufficient conditions hold, the can use the following pseudo-code for finding the value function:
  - 1. Make a guess for  $V_0$  for all values of capital.
  - 2. Apply the operator T and recover  $V_1 = TV_0$
  - 3. Compute distance between  $V_0$  and  $V_1$ .
    - 3.1 If  $V_1$  and  $V_0$  are close enough, stop.
    - 3.2 Otherwise set  $V_0 = V_1$  and go back to 2.
- Once the algorithm has converged, you can simulate the path for capital of an economy with an initial capital endowment.

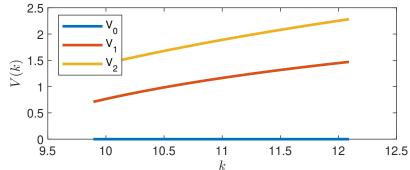

#### Value Function Iteration

- Define a grid with N points of capital between  $[\underline{k}, \overline{k}]$  around the steady state level of capital.
- Define a value of  $V_0$  for all the points in this grid. Let's say  $V_0 = 0$  for all k.
- Given this  $V_0$ , we can generate a vector for each level of capital  $k_i$  which elements are:

$$\begin{bmatrix} u(f(k_i) + (1 - \delta)k_i - k_1) + \beta V_0(k_1) \\ u(f(k_i) + (1 - \delta)k_i - k_2) + \beta V_0(k_2) \\ \vdots \\ u(f(k_i) + (1 - \delta)k_i - k_N) + \beta V_0(k_N) \end{bmatrix}$$

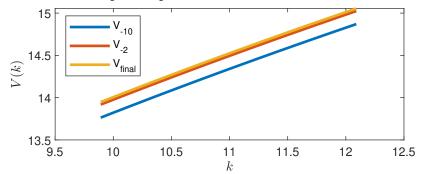

#### Value Function Iteration

- $TV_0(k)$  can be approximated by the maximum value of the elements of this vector.
- Looping through all values of  $i \in [0, N]$  we will recover  $V_1$ .
- Given  $V_1$  we can recover  $V_2$ .

#### Value Function Iteration

• We iterate until  $V_g$  and  $V_{g+1}$  are sufficiently close

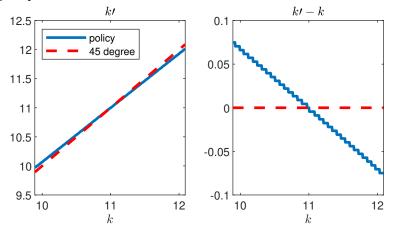

Value Function Iteration

• Now that we have V, we need to recover  $\pi(k)$  which is given by:

$$\pi(k) = \arg\max_{k'} \{u(k, k') + \beta V(k')\}$$

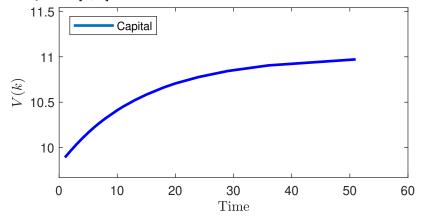

What do we aim for?

· A policy function:

#### Evolution of capital

• Given  $\pi(k)$  we can simulate the transition towards the steady state for any  $k_0 \in [\underline{k}, \overline{k}]$ .

#### Arrow-Debreu Equilibrium

- We will now define three different ways of decentrilizing the nonstochastic one-sector growth model.
- A representative household who owns the capital and labor, which she rents it to firms in exchange of an interest rate  $r_t$  and wage  $w_t$  in units of consumption good a time t per unit of capital rented and labor used.
- There is a market at time 0 where agents can buy and sell goods of different time periods.
- We assume that all contracts that are agreed at time 0 are honored.
- There is a price p<sub>t</sub> for a consumption good at time t relative to consumption goods at t = 0 (Normalize:  $p_{t_0} = 1$ ).

#### Arrow-Debreu Equilibrium

• Consumer's problem:

$$\max_{\{c_t, k_{t+1}\}_{t=0}^{\infty}} \sum_{t=0}^{\infty} \beta^t u(c_t)$$
s.t. 
$$\sum_{t=0}^{\infty} p_t(c_t + k_{t+1}) = \sum_{t=0}^{\infty} p_t((1+r_t)k_t + w_t)$$

Firm's problem:

$$\max_{k_t,l_t} p_t(f(k_t,l_t) - (r_t + \delta)k_t - w_t l_t)$$

#### Arrow-Debreu Equilibrium

#### Definition

- A competitive equilibrium in this economy is a set of sequence of prices  $\{p_t, r_t, w_t\}_{t=0}^{\infty}$  and quantities  $\{c_t, k_{t+1}\}_{t=0}^{\infty}$  such that:
  - 1. Given prices,  $\{c_t, k_{t+1}\}_{t=0}^{\infty}$  solve the household problem.
  - 2. Given prices,  $\{k_t\}_{t=0}^{\infty}$  solve the firms problem.
  - 3. Markets clears:

$$c_t + k_{t+1} = f(k_t) + (1 - \delta)k_t$$

#### Sequential Equilibrium

- Suppose now that agents rent capital and labor to firms in return of  $r_t$  and  $w_t$  period by period.
- Consumer problem:

$$\max_{\{c_{t}, k_{t+1}\}_{t=0}^{\infty}} \sum_{t=0}^{\infty} \beta^{t} u(c_{t})$$
s.t.  $c_{t} + k_{t+1} = w_{t} + (1 + r_{t})k_{t} \ \forall \ t$ 

$$\lim_{t \to \infty} \frac{k_{t+1}}{\prod_{s=1}^{t} (1 + r_{s})} \ge 0$$

• As the firm's problem is static, is identical as before.

#### Sequential Equilibrium

- A sequential market equilibrium is a sequence of prices  $\{r_t, w_t\}_{t=0}^{\infty}$  and quantities  $\{c_t, k_t\}_{t=0}^{\infty}$  such that:
  - 1.  $\{c_t, k_{t+1}\}_{t=0}^{\infty}$  solve the household problem.
  - 2.  $\{k_t\}_{t=0}^{\infty}$  solve the firms problem.
  - Markets clear:

$$c_t + k_{t+1} = f(k_t) + (1 - \delta)k_t$$

#### Recursive Competitive Equilibrium

- Note that when we study dynamic programming approach for solving infinite horizon problems our focus was on policy functions and not on optimal sequences.
- In a recursive competitive equilibrium, the quantities and prices are defined as functions of the state.
- Hence, in a recursive competitive equilibrium both individual decisions (characterized by a value function and a decision rule) and the prices will be functions of the state.

- It is not straightforward to represent the household problem in recursive form because prices are not constant.
  - They depend on the aggregate level of capital:

$$r_t = f_k(K) - \delta$$
$$w_t = f_l(K)$$

- Therefore the future continuation value will depend not only on how many assets are left for the next period but also on these prices.
- The idea is to include aggregate capital as a state variable for the household's problem.

$$V(k, K) = \max_{c, k'} \{ u(c) + \beta V(k', K') \}$$
s.t.  $c + k' = w(K) + (1 + r(K))k$ 
 $K' = G(K),$ 

where G(K) is the agent perceived law of motion of aggregate capital.

#### Definition

- A recursive competitive equilibrium is a perceived law of motion G(K), a policy function g(k,K), a lifetime utility level V(k,K), and a price system r(K), w(K) such that
  - 1. V(k, K) solves the household problem, and g(k, K) is the associated policy function.
  - 2. Prices are competitively determined by firms FOCs.
  - 3. Consistency is satisfied:

$$G(K) = g(K, K)$$

4. Market clears:

$$c + G(K) = F(K) + (1 + \delta)K$$

• The third condition states that, whenever the individual consumer is endowed with a level of capital equal to the aggregate level, his own individual behavior will exactly mimic the aggregate behavior.

#### Algorithm

- We could use the following pseudo-code for solving for the RCE:
  - 1. Make a guess of G(K)
    - 1.1 Make a guess for  $V_0$  for all values of k and K
    - 1.2 Apply the operator T and recover  $V_1 = TV_0$  given the guess of G(K)
    - 1.3 If  $V_1$  and  $V_0$  are close enough, go to 2. Otherwise set  $V_0=V_1$  and back to 1.1
  - 2. From 1.3 recover the policy function g(K, K). If g(K, K) and G(K) are close enough, stop. Otherwise set G(K) = g(K, K) and go back to 1.1

### Adding Uncertainy

- A wide range of interesting economic models involve some degree of uncertainty (aggregate or individual-level).
- To avoid the use of measure theory, we focus on economies in which stochastic variables take finitely many values.
- This restriction enables us to use Markov chains, instead of general Markov processes, to represent uncertainty.

# The NGM with Uncertainty

 Now, we focus on another application: the stochastic version of neoclassical growth model where shocks are going to affect firm's productivity.

$$y(z,k)=e^z f(k)$$

- We are going to assume that stochastic variables can take finitely many values.
- This restriction allows us to use Markov chains to represent uncertainty.

#### The Social Planner Problem

• The recursive formulation of this problem can be written as:

$$V(k,z) = \max_{k'} \left\{ u(k,k',z) + \beta E_{z'|z}[V(k',z')] \right\}$$
  
s.t.  $k' \in \Gamma(k,z) \equiv [0, e^z f(k) + (1-\delta)k]$   
 $z' = \rho z + \epsilon, \ \epsilon \sim N(0, \sigma_{\epsilon}^2)$ 

# Discretize an AR(1) using the Tauchen Method

• Method for discretizing an AR(1) process in N points.

$$z_t = \rho z_{t-1} + \epsilon, \epsilon \sim N(0, \sigma_{\epsilon}^2)$$

- Unconditional variance:  $\sigma_z^2 = \frac{\sigma_\epsilon^2}{1-\rho^2}$
- 1. Create a (equally spaced) grid with first and last point in the grid q standard deviations away from the mean:  $z_1 = -q\sigma_z$ ,  $z_N = q\sigma_z$ 
  - ► Space between points:  $dz = \frac{z_N z_1}{N 1}$
- 2. Fill the transition matrix  $\Pi$ :

$$\Pi(z_j|z_i) = Pr\left[z_j - dz/2 \le \rho z_i + \epsilon \le z_j + dz/2\right]$$

$$= \Phi\left[\frac{z_j + dz/2 - \rho z_i}{\sigma_{\epsilon}}\right] - \Phi\left[\frac{z_j - dz/2 - \rho z_i}{\sigma_{\epsilon}}\right]$$

DYNAMIC OPTIMIZATION Jesús Bueren 58

#### Blackwell's sufficient conditions

• Let's define the operator T over function  $V^g$  as:

$$TV^{g}(k_{t}, z_{t}) = \max_{k_{t+1}} \{u(k_{t}, k_{t+1}, z_{t}) + \beta \sum_{z_{t+1}} \Pi(z_{t+1}|z_{t})V^{g}(k_{t+1}, z_{t+1})\}$$

 Is operator T a contraction mapping? Are Blackwell's sufficient conditions satisfied?

#### Blackwell's Sufficient Conditions

• Monotonicity: If  $V(k_t, z_t) \leq W(k_t, z_t)$  for all  $k_t$  and  $z_t$ :

$$TV(k_{t}, z_{t}) = \max_{k_{t+1}} \{u(k_{t}, k_{t+1}, z_{t}) + \beta \sum_{z_{t+1}} \Pi(z_{t+1}|z_{t})V(k_{t+1}, z_{t+1})\}$$

$$= u(k_{t}, g_{v}(k_{t}, z_{t}), z_{t}) + \beta \sum_{z_{t+1}} \Pi(z_{t+1}|z_{t})V(g_{v}(k_{t}, z_{t}), z_{t+1})$$

$$\leq u(k_{t}, g_{v}(k_{t}, z_{t}), z_{t}) + \beta \sum_{z_{t+1}} \Pi(z_{t+1}|z_{t})W(g_{v}(k_{t}), z_{t+1}) \leq TW(k_{t}, z_{t})$$

Discounting:

$$T[V(k_t, z_t) + a]$$

$$= \max_{k_{t+1}} \{ u(k_t, k_{t+1}, z_t) + \beta \sum_{z_{t+1}} \Pi(z_{t+1}|z_t) (V(k_{t+1}, z_{t+1}) + a) \}$$

$$= T[V(k_t, z_t)] + \beta a$$

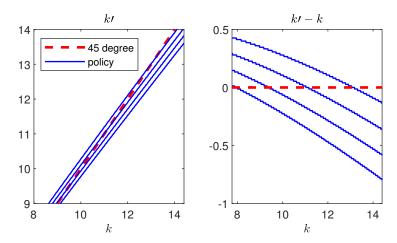

# Discrete State-Space Methods: Value Function Iteration

• Make a guess of  $V^0$  and loop over all combinations of capital and shocks and solve for:

$$V^{1}(k_{i}, z_{j}) = \max_{k' \in K} U(e^{z_{j}} f(k_{i}) + (1 - \delta)k_{i} - k') + \beta \sum_{z'} \Pi(z'|z_{j}) V^{0}(k', z')$$

• If  $V^1$  and  $V^0$  are different, then set  $V^0 = V^1$  and iterate until convergence.

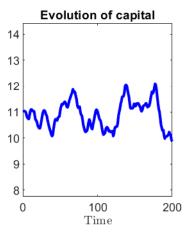

# Policy function

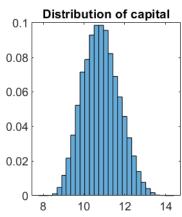

62 DYNAMIC OPTIMIZATION Jesús Bueren

#### Simulation

Now we don't reach an steady state level of capital but a stationary distribution for capital.

DYNAMIC OPTIMIZATION Jesús Bueren 63

#### The Social Planner

#### Characterizing the Solution

Taking first-order conditions from recursive formulation we get:

$$\begin{split} &\frac{\partial u(k,k',z)}{\partial k'} + \beta E_{z'|z} \frac{\partial V(k',z')}{\partial k'} = 0 \\ &u_c(k,k',z) = \beta E_{z'|z} \Big[ (e^{z'}f'(k') + 1 - \delta) u_c(k',k'',z') \Big] \end{split}$$

#### Decentralized Solution

- Let's now decentralize the stochastic one-sector growth model.
- As in the previous chapter we will define three ways of decentralizing :
  - 1. Arrow-Debreu.
  - 2. Sequential Equilibrium.
  - 3. Recursive Competitive Equlibrium.

#### Arrow-Debreu

- We now assume that there is a market at time 0 for each consumption commodity
- The household problem is given by:

$$\max_{\{c_t(z^t), k_{t+1}(z^t)\}_{t=0}^{\infty}} \sum_{t=0}^{\infty} \beta^t \sum_{z^t} \pi(z^t) u(c_t(z^t))$$

$$\sum_{t=0}^{\infty} \sum_{z^t} p_t(z^t) [c_t(z^t) + k_{t+1}(z^t)] \le$$

$$\sum_{t=0}^{\infty} \sum_{z^t} p_t(z^t) [(1 + r_t(z^t)) k_t(z^{t-1}) + w_t(z^t))]$$

The firm's problem is given by:

$$\max_{k_t} p_t(z^t) \Big( e^{z_t} f(k_t(z^t)) - (r_t(z^t) + \delta) k_t(z^t) - w_t(z^t) \Big)$$

#### Arrow-Debreu

- The Arrow-Debreu date-0 competitive equilibrium is a sequence of prices  $\{r_t(z^t), w_t(z^t), p_t(z^t)\}_{t=0}^{\infty}$  and quantities  $\{c_t(z^t), k_{t+1}(z^t), \}_{t=0}^{\infty}$  such that
  - 1.  $\{c_t(z^t), k_{t+1}(z^t), \}_{t=0}^{\infty}$  solve the household problem.
  - 2. Given prices  $\{r_t(z^t)\}_{t=0}^{\infty}$  and  $\{z_t\}_{t=0}^{\infty}$ ,  $\{k_t(z^t)\}_{t=0}^{\infty}$  solves the firms problem.
  - 3. Markets clears:

$$c_t(z^t) + k_{t+1}(z^t) = (1 - \delta)k_t(z^{t-1}) + e^{z_t}f(k_t(z^{t-1}))$$

#### Arrow-Debreu

• Using household FOCs wrt to  $c_t(z^t)$ :

$$\beta^t \pi(z^t) u_c(c_t(z^t)) = p_t(z^t) \lambda$$

• Using household FOCs wrt to  $k_{t+1}(z^t)$ :

$$p_t(z^t) = \sum_{z^{t+1}} p_{t+1}(z^{t+1})(1 + r_{t+1}(z^{t+1}))$$

Using firms FOCs wrt to k<sub>t</sub>(z<sup>t</sup>):

$$r_t(z^t) + \delta = e^{z_t} f_k(k_t(z^{t-1}))$$

#### Arrow-Debreu

Using HH FOCs we get:

$$u_c(c_t(z^t)) = \sum_{z^{t+1}} \frac{\lambda \rho_{t+1}(z^{t+1})}{\beta^t \pi(z^t)} (1 + r_{t+1}(z^{t+1}))$$

and introducing firm's FOC:

$$u_{c}(c_{t}(z^{t})) = \sum_{z^{t+1}} \frac{\lambda p_{t+1}(z^{t+1})}{\beta^{t} \pi(z^{t})} (e^{z_{t+1}} f_{k}(k_{t+1}(z^{t})) + 1 - \delta)$$

separately taking derivative of HH FOC wrt to  $c_{t+1}(z^{t+1})$ :

$$\beta^{t+1}\pi(z^{t+1})u_c(c_{t+1}(z^{t+1}))=p_{t+1}(z^{t+1})\lambda$$

or equivalently

$$\frac{\lambda p_{t+1}(z^{t+1})}{\beta^t \pi(z^t)} = \beta \pi(z^{t+1}|z_t) u_c(c_{t+1}(z^{t+1}))$$

#### Arrow-Debreu

• Therefore we arrive at the same Euler equation than with the social planner:

$$u_c(c_t(z^t)) = \sum_{t=1}^{n} \beta \pi(z^{t+1}|z_t) u_c(c_{t+1}(z^{t+1})) (e^{z_t} f_k(k_{t+1}(z^t)) + 1 - \delta)$$

### Sequential Markets

• In the sequential markets equilibrium household problem is written as:

$$\max_{\substack{\{c_t(z^t), k_{t+1}(z^t), a_{t+1}(s_{t+1}, s^t)\}_{t=0}^{\infty} \\ c_t(z^t) + k_{t+1}(z^t) \leq (1 + r_t(z^t)) k_t(z^{t-1}) + w_t(z^t) \ \forall z^t} \\ \lim_{t \to \infty} \frac{k_{t+1}(z^t)}{\prod_{s=0}^t (1 + r_s(z^s))} \geq 0 \ \forall \ z^t$$

• Given that we have a representative agent and that Arrow-securties need to be in zero net supply, we can eliminate them.

# Sequential Markets

- A sequential market equilibrium in this economy is a set of prices  $w_t(z^t)$ ,  $r_t(z^t)$  and a set of allocations  $c_t(z^t)$  and  $k_{t+1}(z^t)$  for all  $z^t$  such that
  - 1. Given prices,  $c_t(z^t)$ ,  $k_{t+1}(z^t)$  solve the consumer's problem.
  - 2. Given prices,  $k_t(z^{t-1})$  solves firm's problem.
  - 3. Markets clear

$$c_t(z^t) + k_{t+1}(z^t) = (1 - \delta)k_t(z^{t-1}) + e^{z_t}f(k_t(z^{t-1}))$$

 We can write the household's DP programming formulation of the competitive equilibrium as:

$$V(k, K, z) = \max_{k'} \{ u(c, k, k') + \beta \sum_{z'} \pi(z'|z) V(k', K', z')$$
s.t.  $c + k' = w(K, z) + (1 + r(K, z))k$ 
 $K' = G(K, z)$ 

Uncertainty does not affect the firm's problem:

$$\max e^z f(K) - (r + \delta)K - w$$

Thus,

$$r(K,z) = e^{z} f_{k}(K) - \delta$$
$$w(K,z) = e^{z} f_{l}(K)$$

- A recursive competitive equilibrium is a set of functions of quantities G(K,z), g(k,K,z), lifetime utility level V(k,K,z), and prices r(K,z), w(K,z) such that:
  - 1. V(k, K, z) solves the household problem, and g(k, K, z) is the associated policy function.
  - 2. Prices are competitively determined by firms FOCs.
  - 3. Consistency is satisfied:

$$G(K,z)=g(K,K,z)$$

4. Markets clear:

$$c + G(K, z) = e^{z} f(K) + (1 - \delta)K$$

#### Algorithm

- We could use the following pseudo-code for computing the RCE
  - 1. Make guess of  $G_0(K, z)$ 
    - 1.1 Make guess of  $V_0$  for all values of k, K and z.
    - 1.2 Apply operator T and recover  $V_1 = TV_0$  given  $G_0(K, z)$ .
    - 1.3 If  $V_0$  and  $V_1$  are close enough go to step 2. Otherwise set  $V_0=V_1$  and back to 1.1
  - 2. From 1.3 recover the policy function  $g_1(K,K,z)$ . If consistency is satisfied,  $g_1(K,K,z) \simeq G_0(K,z)$ , stop. Otherwise, set  $G_0(K,z) = g_1(K,K,z)$  and go back to 1.1
